Designs for wireless networks are being continuously updated as scientists and engineers strive to improve the overall performance of these networks. For example, if the amount of signal interference generated by a wireless network increases, throughput and the quality of service of the network decreases. Consequently, measures to prevent interference and/or maximize the amount of usable signal are taken. As one example, a wireless device may operate at a frequency that is adjacent to another frequency that is used by another device. In these situations, a different frequency may be used by the other device and the interference is likely to occur. Designing a wireless network to avoid interference is, however, difficult, particularly if the interfering signals are multiple-access signals. A single-access signal is the signal transmitted by a wireless device for a single purpose (e.g., with the signal) being received and used by a first receiving device; whereas a multiple-access signal is transmitted by a wireless device for multiple purposes (e.g., with the signal) being received and used by multiple receiving devices. For example, a single-access signal may be a signal transmitted from a second wireless device (with the signal) to a first wireless device (with the signal); whereas a multiple-access signal may be a signal transmitted from a second wireless device (with the signal) to multiple first wireless devices (with the signal). What is needed, then, are techniques for designing a wireless network that avoid interference between wireless devices.Progression of HIV-1 resistance to nucleoside and non-nucleoside analogues is variable among different regions, suggesting that molecular epidemiology studies could be useful for regional surveillance. The development of resistance to antiretroviral therapy in patients with HIV-1 infections, resulting in therapeutic failure, is variable and depends upon the presence of mutations in the viral reverse transcriptase (RT) and other gene regions such as the protease (PR) and integrase (IN), as well as variations in viral load. These variations contribute to local variations in the frequency of cross-resistance. The knowledge of which mutations exist and their prevalence can provide important information for clinical decision-making. The question of whether new mutations, or the existence of mixed infections, are more likely to appear in certain regions, has not been adequately addressed. We examined, for a total of 1006 samples from 454 patients who were being treated in 17 European countries, whether there was regional variability in the emergence of nucleoside RT inhibitor (NRTI) and non
